

Exercise 2

Objectives:

1. Investigation of point measurement accuracy using GIS-level GNSS receivers in three different conditions with and without averaging.
2. Getting experience in using statistical tools.

According to the given tasks the points in three different environments, such as open, urban, and vegetated area have been choose. Chosen point for open environment was located on sport field of UWH, for urban environment in Frankenburg Street, and for vegetated environment was located in territory of Botanic garden. Field observation works have been done with Leica 1200 series with geodetic accuracy and GIS-level GNSS receiver Trimble Juno. The field measurement works were started with GIS-level GNSS receiver Trimble-Juno and each marked points were measured twice per each day during five days. The cause of double measurement of each point was that the first time it was measured without averaging and the second time with averaging. For a second measurement time for observation was assigned for the 30 seconds and result of it was averaged. The difference between two measurements on each point was within 2-3minutes. The points, which were observed by help of specialised GPS receiver Leica 1200, were assigned as reference points. During the field measurement works with GPS receiver Leica 1200 the weather was clear and RTK observation method had been used.

For purposes of accuracy assessment and determining distribution of observed points around reference points **RStudio** software had been used. The office work was started with downloading all data from devices. Further all gathered data was entered to excel sheet in a form of table and saved as file with .csv extension. After, that file was imported to **RStudio** software environment. First step in **RStudio** was to plot the graphs about distribution of measured points with Trimble Juno around reference points (Figures 1:3). The second step was to plot a graph from, which it could be possible to determine dependency of PDOP from number of tracking satellites. And the third step was to numerically calculate and define errors of measured points in **Euclidean distance** from ground truth point in 2D and 3D spaces. For this purpose **Euclidean formula** $d(p,q)=\sqrt{(q_1 - p_1)^2 + (q_2 - p_2)^2 + \dots \dots (q_n - p_n)^2}$ have been used.

Where: d-distance, q and p- Euclidean vectors, p is refers to the origin point in Euclidean space.

Table 1: .CSV extension file, which was imported to **RStudio** environment.

Figure below shows points distribution around ground truth point, which was observed in open area.

Figure below shows points distribution around ground truth point, which was observed in build-up area.

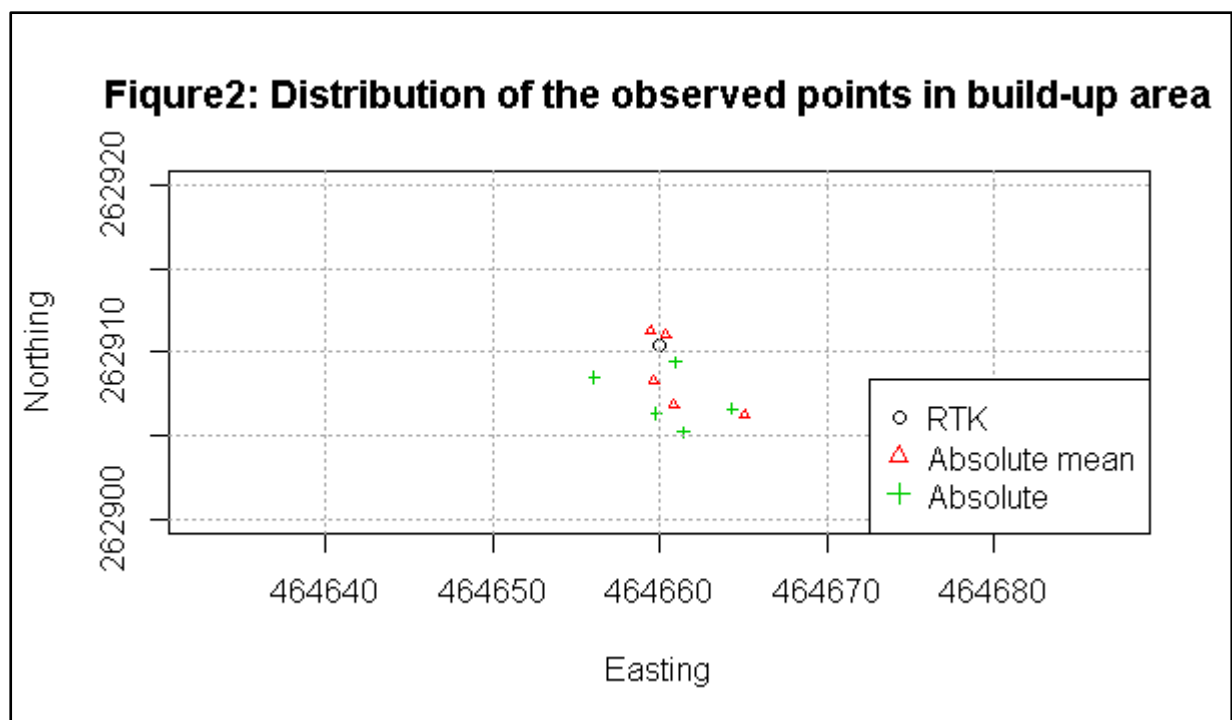

Figure below shows points distribution around ground truth point, which was observed in vegetated area.

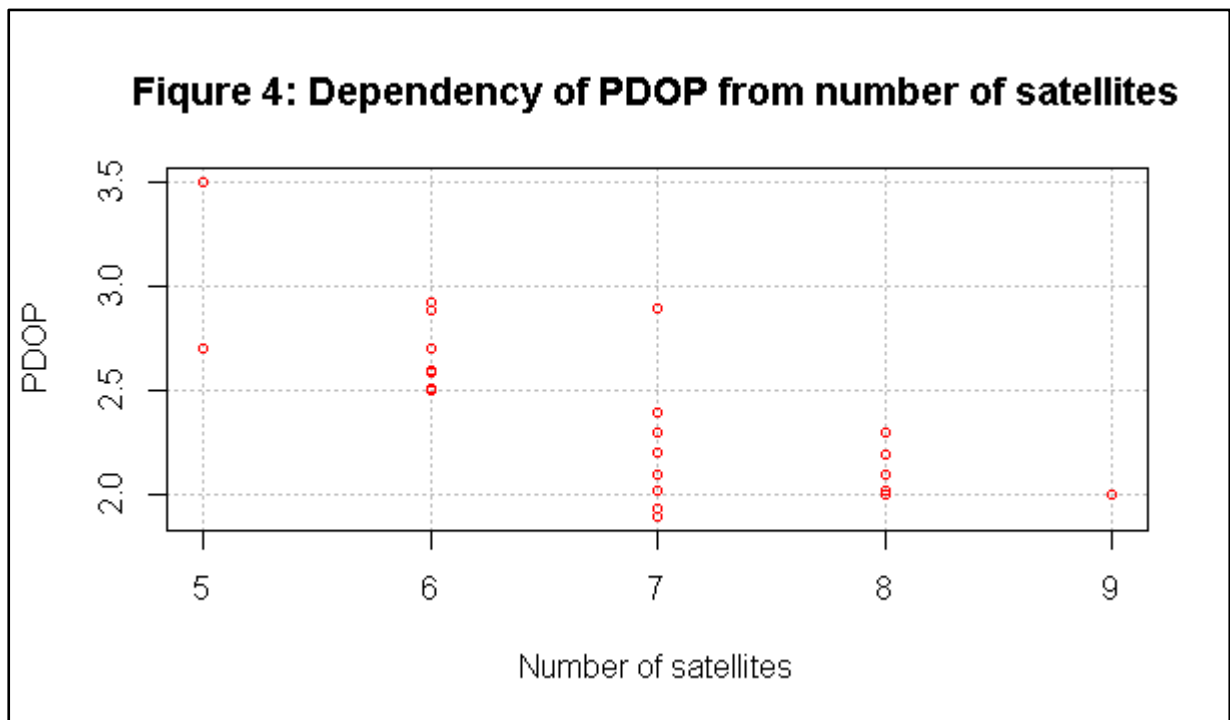

Figure below shows dependency of PDOP from number of tracking satellites.

Example of calculating Euclidean distance from the measured points to a reference point by help of “RStudio” software.

```

1 # only one point
2 sqrt((field[1,5]-RTK[1,2])^2+(field[1,6]-RTK[1,3])^2+(field[1,7]-RTK[1,4])^2)
3
4 ## This two distance calculation the same vectorising technique
5 sqrt((field[1:30,5]-RTK[1,2])^2+(field[1:30,6]-RTK[1,3])^2+(field[1:30,7]-RTK[1,4])^2)
6
7 sqrt((field[1:nrow(field),5]-RTK[1,2])^2+(field[1:nrow(field),6]-RTK[1,3])^2+(field[1:nrow(field),7]-RTK[1,4])^2)
8
9
10 ## Use some specialised function
11 dist(field[1:3,5:6])
12
13 ## use as matrix
14 as.matrix(dist(field[1:3,5:6]))

Table 2: Result of calculating Euclidean distance between a reference point and the measured points in 3D (X, Y, Z) space.

Differences of the observed points in different days from a reference point						
Environment	Method	1 day	2 day	3 day	4 day	5 day
Open area	single	24.5837	7.231171	23.20436	11.95997	16.28679
	averaged	17.22522	5.734621	22.97523	4.493532	24.40095
Build-up area	single	25.36333	10.84325	19.88873	12.45529	23.0189
	averaged	19.27336	10.6185	20.58276	13.19683	25.04428
Vegetated	single	12.39756	16.6208	26.41351	2.632888	31.72941
	averaged	13.02263	21.52417	33.40135	4.866876	37.30284

Table 3: Result of calculating Euclidean distance between a reference point and the measured points in 2D (X, Y) space.

Differences of the observed points in different days from a reference point						
Environment	Method	1 day	2 day	3 day	4 day	5 day
Open area	single	8.609031	3.48314	2.697753	2.843637	4.884793
	averaged	4.500134	1.529099	1.487891	1.777554	5.695229
Build-up area	single	4.0555	5.357971	4.350876	5.753083	1.388247
	averaged	0.794028	3.689266	1.029412	6.549304	2.089069
Vegetated	single	1.495756	5.075124	19.03053	2.545421	7.046788
	averaged	1.305741	8.06275	5.430132	1.745747	8.77106

Conclusion: From the figures, which are shown above it's not clear, that averaging is improving the accuracy of measurement or not, because by visual interpretation it's difficult to distinguish it. However it was clear by interpreting Figure 4, that quality of PDOP directly **depend** from number of tracking satellites by receiver. Concerning question does averaging improving accuracy or not?.

By interpreting Table 2 it is difficult to say that averaging improves accuracy, yes somewhere it is improving, but somewhere it shows worse result than single measurement in 3D space. It has to be note that environmental condition should be considered when the users going to choose either averaging or non-averaging methods.

By interpreting Table 3, which showing Euclidean distance between ground truth point and measured points in 2D space it's clear, that averaging is enhancing accuracy. So it can be say the averaging method maybe is not sophisticated for determining position in 3D space, but obviously it is clear, that this method is more accurate and reliable for horizontal positioning than single measurement.
